

1. Bit stuffing

a)

Bit string before bit-stuffing = 10011111100101111100011 → 1001111101001011111000011

After bit-stuffing = 10011111010010111111000011

b)

Received bits before de-stuffing = 01111110001111110110011111001101111110

0111111000111110110011111001101111110

After de-stuffing = 0111111000111111001111101101111110

2. Link Layer Protocols

Channel bit rate = 4Kb/s, $T_{prop} = 20\text{ms} = 20\text{E-}3\text{s}$

50% link utilization = $0.5 * 4\text{Kb/s} = 2\text{Kb/s} = 2 * 2^{10} \text{ bits/s}$

$2 * 2^{10} \text{ bits/s} \leq \text{frame_size} / \text{RTT}$

$\text{RTT} = 2 * T_{prop} = 2 * 20\text{E-}3\text{s} = \text{RTT} = 40\text{E-}3\text{s}$ or 40ms (assuming transmission time of ack by receiver negligible)

$2 * 2^{10} \text{ bits/s} \leq \text{frame_size} / 40\text{E-}3\text{s} \rightarrow (2 * 2^{10} \text{ bits/s})(40\text{E-}3\text{s}) \leq \text{frame_size}$

Therefore frame_size must be at least 81.92 → 82 bits for 50% utilization

100% utilization happens when $\text{frame_size} = 4 * 2^{10} \text{ bits/s} * 40\text{E-}3 \text{ s} = 163.84 \rightarrow 163 \text{ bits}$ (round down b/c cannot exceed 100% utilization)

Therefore the range frame sizes to give at least 50% link utilization efficiency:

82 bits \leq frame size \leq 163 bits

3. Distance Vector Routing

C's new routing table after update from B,D and E

Destination	Cost	Route
A	11	C→B→A
B	6	C→B
C	0	C
D	3	C→D
E	5	C→E
F	8	C→B→F

4. TCP Sequence Numbers

Consider an optical fiber link that can run at 75 terabits/second ($75 * 2^{40}$ bits/s)

Consider TCP using 64 bit sequence numbers (2^{64} sequence numbers total)

What is maximum packet lifetime to prevent sequence number wrap around?

1 sequence number = 1 byte

$2^{64} \text{ bytes} / ((75 * 2^{40}) / 8) \text{ bytes/second} = 1.789\text{E6 seconds for byte (sequence number)}$

lifetime = about 20.7 days

NOTE: below was done considering packets, I spoke to Prof Bletsch and he said just the answer above was needed but I included these anyway...

Assuming max packet size of 64KB:

Maximum packet lifetime = $1.789\text{E6 seconds/byte} / (64 * 2^{10}) \text{ bytes} = 27.3 \text{ seconds}$

Assuming 1460 byte size packet (noted in lecture slides as common for fitting in 1 ethernet frame with IP and TCP headers):

Maximum packet lifetime = $1.789\text{E6 seconds/byte} / 1460 \text{ bytes} = 1225.34 \text{ seconds}$

5. DNS

WHOIS LOOKUP

duke.edu is already registered*
